Figure 2. Microscopic findings for patient 2.

**Left.** A conventional hematoxylin–eosin stain shows only rare islands of surviving regenerative lobular cellularity (arrow). (Original magnification, × 5.) **Middle.** Reticulin silver staining demonstrates dense condensation of fibers surrounding persisting ducts without any intervening lobules, except in the regenerative nodule (arrow). (Original magnification, × 5.) **Right.** Immunohistochemical stain for cytokeratin cocktail AE1/AE3 highlights the dense aggregates of ducts (arrows) uninterrupted by lobular elements. (Original magnification, × 5.)
